

### A symmetric 1-electron system: $H_2^+$

The energy  $E(R)$  depends to the distance  $R$  between the nuclei.

If  $R \rightarrow \infty$ , then  $E = H_{AA}$ , the energy of a hydrogen atom plus the proton.

If  $R$  gets smaller, the lowest energy is  $E_{low}$  and the electron occupies the  $\sigma$  state.

If  $R$  gets too short, the nuclear repulsion increases the energy again.

The lowest energy  $E(R_{eq})$  at  $R = R_{eq}$  is the equilibrium bond energy of  $H_2^+$ :

### Diagonalizing the minimal basis (2x2) matrix for an asymmetric 1-electron system, $HeH^{++}$
